Welcome to CPSC 441!

Today's Tutorial

- **Introduction to C**
- **Library**
- **Array**
- **Structure**
- **String**
- **Standard I/O**
- **File I/O**

Welcome to CPSC 441 

Tools before you start

- **C/C++ Compiler**
 - Windows: Code::Blocks
 - Linux: gcc
 - Mac OS X: XCode
- **IDE (Integrated Development Environment)**
 - NetBeans/Eclipse

Simple C Example

```
// c
#include <stdio.h>

int main(int argc, char *argv[]) {
    printf("Hello world!\n");
    return 0;
}
```

Welcome to CPSC 441

Compiling C in Linux

- gcc invokes C compiler
- gcc translates C program into executable for some target
- default file name a.out

- Example: compile and run hello.c

```
$ gcc hello.c
```

```
$ a.out
```

```
Hello, World!
```

```
$ gcc hello.c -o hello
```

```
$ ./hello
```

```
Hello, World!
```

Welcome to CPSC 441

More options

- Some useful command line options:
- [-o file]: specifies the output file for object or executable
- [-Wall]: show all warnings (highly recommended)
- [-l libnam]: Links the library libname, e.g., -lxnet
- If you get errors saying the library cannot be found, make sure the path is correctly set, and you do have the libraries you need.

Libraries

- C provides a set of standard libraries for

numerical math functions	<code><math.h></code>	<code>-lm</code>
character strings	<code><string.h></code>	
character types	<code><ctype.h></code>	
I/O	<code><stdio.h></code>	

- `#include <math.h>`
careful: `sqrt(5)` without header file may give wrong result!
- `gcc -o a main.c -lm`

Main arguments

```
int main(int argc, char *argv[])
```

- argc: number of arguments passed to the program
- argv: pointers that list all of the arguments
 - Name of executable + space-separated arguments
 - Name of executable is stored in argv[0]
- \$ a.out 1 23 'third arg'
- The return value is int
 - convention: 0 means success, > 0 some error

Array

- Array declaration: `int a[100];`
- C/C++ arrays have no length parameter!
Note: when passing an array to a function, typically you have to pass the array size as a separate argument as well.
- You have to take care of array bounds yourself
- `int input[10];`
- `input[10] = 20; // out of bound!`
- `input[-1] = 5; // out of bound!`
- This code could compile and run, but most likely, you'll see unexpected behavior or crash your program.
- Array's name is a pointer to its first element

Structure

- C struct is a way to logically group related types
 - Is very similar to (but not same as) C++/java classes
 - store many different values in variables of potentially different types under the same name.
- A struct component can be of any type (including other struct types)
- Example:

```
struct database {  
    int id_number;  
    int age;  
    float salary; };
```

```
int main() {  
    struct database employee;  
    employee.age = 22;  
    employee.id_number = 1;  
    employee.salary = 12000.21;  
}
```

Welcome to CPSC 441

String - 1

- In C, string is an array of **char** terminated with “\0” (a null terminator: ‘\0’)
 - “hello” = hello\0

- Declaring and initialize a string

```
char str[]="hello"; //initialized string
```

```
char *strp="hello"; // a char pointer
```

String - 2

- What if the size of string is not fixed? (e.g. the string is input by user every time it runs)
- Make use of malloc(size)

```
char *ptr;  
unsigned int size;  
ptr=malloc(size);  
//The pointer returned value NULL if there's no memory  
left. Should be checked every time!  
int returncode;  
returncode=free(ptr);  
//The return code is 0 if the release is successful
```

String - 3

- Some useful string handling functions: (remember header: <string.h>)

```
char *str1, *str2;
```

- **strlen()** - give the length of string (not include "\0")

```
int len;  
len=strlen(str1);
```

- **strcpy()** - copy a string from one place to another

```
strcpy(str1,str2);
```

- **strstr()** - test whether a substring is present in a larger string

```
int location;  
location=strstr(str1,str2);  
//if str2 is present in str1, return the first location; otherwise,  
return null
```

- **strcmp()** - compare two strings

```
int value;  
value=strcmp(str1,str2);  
//if two strings are identical, return 0; otherwise indicating the  
ASCII order
```

String - 4

- Example

Example 22 from

<http://www.iu.hio.no/~mark/CTutorial/CTutorial.html#Strings>

Standard I/O - 1

```
#include <stdio.h>
```

- Formatted I/O

```
int scanf(const char *format, ...)
```

- read from standard input and store according to format (ignore space)

```
int printf(const char *format, ...)
```

- write to standard output according to format

Example:

```
int this_is_a_number;  
printf( "Please enter a number: " );  
scanf( "%d", &this_is_a_number );  
printf( "You entered %d", this_is_a_number );
```

Welcome to CPSC 441

Standard I/O - 2

```
#include <stdio.h>
```

- Formatted I/O

gets() - fetches a string from standard input file (which is keyboard here) and put into buffer (compulsory)

```
#define SIZE 255;
char *sptr, buffer[size];
sptr=gets(buffer);
//gets() stop reading when it finds a new line character
```

puts() - sends a string to output file until it finds a NULL. A new line character will be written instead of NULL.

```
int returncode;
char *sptr;
returncode=puts(sptr);
```

Welcome to CPSC 441

File I/O - 1

- `FILE *fopen(const char *path, const char *mode)`
 - open a file and return a FILE pointer. Can use the FILE pointer perform input and output functions on the file
 - Mode:
 - r Open file for reading
 - w Open file for writing
 - a Open file for appending
 - rw Open file for reading and writing (some systems)

e.g. `FILE *fp;`

```
if ((fp = fopen ("c:\\test.txt","r")) == NULL)
    { printf ("File could not be opened\n");
      error_handler(); }
```

//if the file is not open successfully, it returns NULL. Always check!!

Welcome to CPSC 441

File I/O - 2

- `fclose()` - close the file, return 0 if success

e.g.

```
if (fclose(fp) != 0)
```

```
{ printf ("File did not exist.\n")
```

```
; error_handler(); }
```

```
//Always check!!
```

- `fprintf()` - same as `printf()`, but it writes to a file

e.g.

```
printf ("Hello world %d", 1);
```

```
fprintf (fp,"Hello world %d", 1);
```

File I/O - 3

- `fscanf()` - same as `scanf()`, but it reads from a file: `fscanf (fp,format,pointers)`

e.g.

```
fscanf (fp, "%d %f %c", &i, &x, &ch);
```

//it's easy to get error when you are using `fscanf`, so be careful!

- `Fgets()` - same as `gets()`, but it reads from a file: `fgets (pointers, n, fp)`

e.g.

```
fgets (strbuff,n,fp);
```
